ABSTRACT

This research report identifies labor market areas (LMAs) that can be used for statistical and planning purposes in research on rural America. It details the process by which the 382 LMAs were delineated, using commuting-to-work data from the 1980 Census. A rationale for identifying LMAs appears first. The next part describes the research procedures used. Factors influencing the selection of a source of commuting data are discussed. Sections that follow explain preliminary data processing and how the data were analyzed with a statistical algorithm known as hierarchical cluster analysis. Procedures used to interpret the cluster analysis results and delineate LMAs are then detailed. The final part presents some preliminary aggregate statistics to help introduce researchers to LMAs. They include their size, location, and a few of their social and economic characteristics. Appendixes, which amount to over one-half of the report, include labor market areas, codes, population, and labor force size; alphabetical listing of counties and codes; and maps of western, southern, north central, and northeastern labor market areas with LMA codes. Labor Market Areas for the United States, by Charles M. Tolbert  
II and Molly Sizer Killian. Agriculture and Rural Economy Division,  
Economic Research Service, U.S. Department of Agriculture. Staff  
Report No. AGES870721.

## ABSTRACT

This report documents the procedures used to delineate 382 labor market areas (geographic areas encompassing both the place of work and the place of residence of a local population) for the United States. The data used to delineate these labor market areas (LMA's) were the 1980 Census journey-to-work data for counties and county-equivalents in the 50 States and the District of Columbia. Matrices of these data were constructed to indicate the relative strength of the commuting ties between each pair of counties. The results of a hierarchical cluster analysis on these matrices were then used to identify groups of counties with strong shared commuting ties.

## THE AUTHORS

Charles M. Tolbert II is an associate professor with the Sociology Department, Florida State University. Molly Sizer Killian is a sociologist with the Agriculture and Rural Economy Division, Economic Research Service, U.S. Department of Agriculture.

1301 New York Avenue, NW.  
Washington, DC 20005-4788

August 1987

## ACKNOWLEDGMENTS

Identifying labor market areas for the United States is a major undertaking. A number of people participated in this project. The market delineation was a collaborative effort involving the Rural Labor Market Section, Agriculture and Rural Economy Division, Economic Research Service (ERS), USDA and State affiliates of USDA Regional Project S-184 (see text footnote 1).

At ERS, Leonard Bloomquist, David McGranahan, and Shelley Pendleton provided hours of valuable assistance in assessing initial results. Decisions about data sources and analysis strategies were made by the S-184 Technical Committee. Members include Glenna Colclough (Alabama-Huntsville); Woong Cho, Edna Martin, and Stella Oqunwole (Alcorn State); Joseph Molnar (Auburn); Lewell Gunter and Patrick Horan (Georgia); Janet Bokemeier and Ann Tickamyer (Kentucky); F. A. Deseran (Louisiana State); William Falk and Matthew Snipp (Maryland); Thomas Lyson (Cornell, formerly Clemson); and H. L. Goodwin (Texas A&M).

At Florida State, Ellen Hofstadter, Ada Haynes, and Steve McClellan served as student research assistants. Paul Hanna, manager, Social Science Computing Services, provided computing expertise.

Robert Coltrane (ERS) was instrumental in early discussions and securing funding for the project. Leslie Whitener (ERS) provided valuable comments on a draft of this report. A very special note of thanks is due Calvin Beale (ERS) for sharing his impressive knowledge of this country and his extensive evaluation of these market areas.

Data analysis and initial delineation of market areas were done by Charles Tolbert at Florida State University. He was also responsible for those portions of this report pertaining to the delineation of market areas. The section containing descriptive profiles of the market areas was researched and written by Molly Sizer Killian (ERS).

# Labor Market Areas for the United States

Charles M. Tolbert II

## INTRODUCTION

The geographic areas of nonmetro America exhibit a great deal of variation in economic and social characteristics. In addition to agricultural areas, nonmetro America includes sparsely populated mountainous regions, millions of acres of heavy forests, small towns, light manufacturing areas, tiny coastal hamlets, and the suburban fringes of growing metro areas. What we know about this heterogeneity is based largely on data for American counties. This means that our understanding of nonmetro diversity comes from data on arbitrary political units.

A fundamental premise of the research reported here is that county boundaries are not adequate confines for an area's economy. A local economy and its labor market are not bounded by the nearest county line, but by interrelationships between buyers and sellers of labor. If we are to understand the diversity of nonmetro America, we need a geographic standard capturing variations in local economic and labor force activities. The central objective of the research described here is to develop such a standard.

This research report identifies labor market areas which can be used for statistical and planning purposes in research on rural America. The 382 labor market areas (LMA's) are based on commuting-to-work data from the 1980 Census and encompass all county and county-equivalents in the 50 States and the District of Columbia. Consistent with U.S. Bureau of the Census confidentiality standards, each LMA has at least 100,000 inhabitants. This document details the process by which these LMA's were delineated.

This labor market identification project is part of a larger research effort organized by officials of the ERS Agriculture and Rural Economy Division, and land-grant university researchers affiliated with USDA Project S-184, "Labor Markets and Labor Differentiation in Nonmetropolitan Areas." <sup>1/</sup> The research reported here partially

<sup>1/</sup> USDA Regional Project S-184 is a research committee of rural sociologists and agricultural economists. University researchers affiliated with the project represent agricultural experiment stations of Alabama, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, and South Carolina. USDA representatives on the project are affiliated with the Rural Labor Markets Section, Agriculture and

fulfills one objective of Project S-184 which is to identify and measure the characteristics of local labor markets as basic units of social and economic organization. Ongoing research efforts focus on the effects of social and economic changes on local labor markets, households, families, and workers.

A unique version of the 1980 Census data has been obtained which employs the labor market specification outlined in this report. Public Use Microdata Sample D (PUMS-D) identifies these LMA's on the household records of individual residents of the market areas. PUMS-D is a 1-percent sample of the U.S. population. This means that the data file contains information on approximately 2.2 million persons. For the smallest market areas, there are at least 1,000 persons in the data file. And, there are many more from larger LMA's (roughly 1 percent of the total local population). A sample of this magnitude allows researchers sufficient data to focus on specific market areas and to conduct comparative research across LMA's.

Labor market identification means that researchers can assess the influence of the local economy on the socioeconomic well-being of workers residing in markets (Horan and Tolbert, 1984; Tolbert, forthcoming). In other words, with data on both individuals and their labor markets, it is possible to study how characteristics of markets affect residents' employment experiences. Researchers are beginning to undertake precisely this kind of work with the PUMS-D data file. This report reviews the steps taken to develop the geography found on PUMS-D.

#### RATIONALE

A labor market is a set of relations between buyers and sellers of labor. A labor market area is a specific locale in which interactions between buyers and sellers of labor take place. Thus, the local area has long been of significant interest to labor market researchers (Wilcock and Sobel, 1958; Thompson, 1965; Hanushek, 1973, 1981; Summers and others, 1976; Parcel, 1979; Horan and Tolbert, 1984).

---

Rural Economy Division (ERS). The project was organized to promote collaboration and sharing of resources among the participants. This delineation of labor market areas is one example of the cooperative research efforts of the group. Another committee accomplishment is the acquisition of the PUMS-D data file from the U.S. Bureau of the Census. That data purchase was made possible by contributions from each participating agency and the Southern Rural Development Center, the Northeast Center for Rural Development, and the North Central Regional Center for Rural Development.

While a variety of strategies has been employed to represent labor markets for statistical purposes, none of the previous approaches is very satisfactory for research on nonmetro employment patterns. In part because of the availability of data on urban areas, Standard Metropolitan Statistical Areas (SMSA's) have been used to represent labor markets (Bowen and Finegan, 1969; Hirsch, 1978; Parcel, 1981). In such applications, rural areas are generally omitted by definition from the research.

Several areal definitions based on groups of counties do include rural areas. In its 1980 Census publications, the Bureau of the Census employs county group designations based on State planning districts and MSA (Metropolitan Statistical Area) boundaries. While nonmetro counties are included in these county group schemes, the criteria for grouping counties vary from State to State. And, as a rule, Census county groups do not cross State lines. While the Census county groups are intended to facilitate State planning and data collection, they are less than satisfactory proxies for labor market areas. We base this assessment on possible inconsistencies in area formulations from State to State and arbitrary intrastate limitations.

Another example of county groups schemes is the Bureau of Economic Analysis' economic areas developed in the 1960's by Berry (1968, 1973). Based on central place theory (Losch, 1959; Christaller, 1966), the BEA county groups contain an urban center and surrounding counties. Commuting-to-work data from the 1960 Census and, later, the 1970 Census were used to place fringe counties in groups. Several researchers have employed the BEA county groups to represent local labor markets (Dunn, 1980; Hanushek, 1981; Horan and Tolbert, 1984). Despite extensive use of the BEA economic areas, they were not conceived as local labor markets and pose particular problems for nonmetro labor market research.

One drawback is the use of substantially dated commuting information. A more serious conceptual problem for nonmetro applications stems from assumptions of the central place model. In theory, nonmetro hinterlands are explicitly treated as subordinate to and dependent upon urban areas. In practice, rural counties were generally grouped around an urban center in the formulation of BEA economic areas, minimizing the number of exclusively nonmetro areas. Since large-scale urban trends can obscure important trends in less populated areas, this urban bias can be an obstacle to the study of nonmetro labor force participation.

The strategy described in this report for delineating county groups in theory permits the study of nonmetro as well as metro labor markets. Unlike other county group schema, the method employed here applies consistent grouping criteria to recent commuting data and does not require a group of counties to have an urban center.

## PROCEDURES

Identification of LMA's began with selection of a source of commuting data. Factors influencing that decision are discussed below. Sections that follow explain preliminary data processing and how the data were analyzed with a statistical algorithm known as hierarchical cluster analysis. Finally, procedures employed to interpret the cluster analysis results and delineate LMA's are detailed.

### Description of Data

Selection of appropriate data for identifying labor market areas involved much research and discussion among participants in this collaborative research effort. The project members agreed that the primary criterion for designating market areas would be commuting data from the 1980 Census. Research by Project S-184 participants suggest no other contemporaneous data for the Nation as a whole.

The decision to use commuting data was based in large measure on the need for an objective and quantifiable basis for delineating market areas. The rationale reflects our definition of a market area as a locale that encompasses both the place of residence and place of work of a local population. And, there is precedent for such an assumption in the literature. Wilcock and Sobel (1958:5) argue that ". . . the place in which jobs are sought and job decisions are made and the local market area, defined in terms of ability to commute to and from jobs are one and the same." The 1980 Census data were selected because they are the most recent and detailed source of information on national commuting patterns.

One potential drawback to the Census journey-to-work data must be noted. In 1980, the Census question was phrased: "At what location did this person work last week?" Instructions that accompanied the Census questionnaire advised respondents working in multiple locations to indicate the place where the workday began or where the most hours were spent. Still, it is possible that some of the data represent nonroutine work locations or, in the case of regularly traveling employees, one of several possible places of work.

We must assume that any errors in reporting place of work are random and tend to cancel one another. A more serious problem would be systematic error introduced into the data by seasonality or some unique event affecting large numbers of persons on Census Day (April 1, 1980). We are aware of no such problems. With these cautions in mind, we deemed the 1980 data the most recent and reliable national information on commuting.

Project participants further agreed that the geographic units of analysis should be counties. While finer detail could be had in metro areas, the inclusion in this research of rural areas meant that county-level data were necessary. Counties are generally employed as

primary statistical units in the study and assessment of nonmetro areas (see, for example, Bender and others, 1985). Researchers were also concerned about the ability to carry out analyses of national as opposed to local scope. While subcounty commuting information could perhaps be obtained on a handful of nonmetro areas, such detailed data collection on a national basis would not be feasible. Compatibility with existing data sources in which counties are the units of analysis was also a priority. Important county-level data series are readily available, such as those in the County and City Data Book (U.S. Bureau of the Census, 1983). The data required, then, were 1980 Census journey-to-work information for counties and county equivalents in the 50 States and the District of Columbia. 2/

Our source for commuting data was a special tabulation by the Census Bureau for the Bureau of Labor Statistics that supplies information on all reported commuting destinations for 3,136 U.S. counties and county equivalents (parishes, consolidated governments, independent cities, and boroughs). In New England, subcounty detail is provided for minor civil divisions (MCD's). The machine-readable data file "Place of Residence by Place of Work" is available from the Census Bureau.

Table 1 contains a reconstruction of a data sample from the "Place of Residence by Place of Work" file. The place of residence is Manatee County, Florida, encompassing the Bradenton area. Thirty-three commuting destinations are listed for the origin county, including a number of Florida counties. But notice also the remote places of work such as Virginia, New York, Illinois, and Michigan. In addition, there are residual categories "at sea," "outside U.S.," and "not reported." These detailed commuting data clearly provide abundant information for delineation of labor market areas.

#### Preliminary Data Processing

Prior to analyzing the commuting data, we undertook several preliminary data processing measures. New England data for MCD origins and destinations were aggregated to the county level. Data for independent cities in Virginia were aggregated with data for counties in which the cities are located. Then preliminary matrices of intercounty commuter flows were constructed, indicating the number of commuters moving from one county to another. These frequency matrices were then transformed into flow matrices that expressed commuting patterns in terms of population proportions. The two sections that follow explain these matrices in detail.

---

2/ The Federal Information Processing Standard (FIPS) definition of counties and county equivalents in effect in 1980 was employed in this research.

Note: First two columns of table contain FIPS State and county codes.

Frequency Matrices. An example of a frequency matrix is presented in table 2. The data in the table are for a set of nine arbitrarily selected counties (referred to as A, B, C, D, E, F, G, H, and I). The rows of the table indicate the counties of residence. The columns represent possible destination counties of work, and the numbers in them indicate how many persons commute to that county from the origin county. The extreme righthand column contains totals across the row or the number of commuting and noncommuting employed persons residing in an origin county. The numbers along the main diagonal are frequencies of persons who reside and work in the same county (that is, workers who do not commute to another county).

County A is the largest of the counties and is an apparent nucleus for commuting patterns for this set of counties. The upper lefthand corner cell indicates that more than 244,000 workers never leave county A as they journey to work. The second cell on the first row indicates that 857 persons commute from county A to county B. Conversely, the first entry on the second row of table 2 means that 1,827 residents of B work in A. The largest off-diagonal numbers in the frequency matrix correspond to counties A and H. And, as the zero cell entries suggest, some counties share no commuters at all.

Several considerations guided the building of frequency matrices for the 50 States and the District of Columbia. First, we were concerned that Western States with larger counties and smaller populations be analyzed separately from Eastern States. Lower populations and larger land areas could lead to weaker commuting relationships between western counties, and combining western and eastern data could produce erroneous results.

Table 2—Frequency matrix for nine sample counties

County of residence	County of destination									Total
	A	B	C	D	E	F	G	H	I	
<u>Number of workers</u>										
A	244,327	857	1,261	300	168	752	390	3,216	450	251,721
B	1,827	45,188	125	0	0	0	0	0	182	47,322
C	3,826	121	14,709	0	12	0	91	18	0	18,777
D	1,808	0	175	16,343	216	0	0	0	0	18,542
E	5,132	14	103	0	5,775	152	5	28	0	11,209
F	6,668	22	7	0	99	5,717	190	181	0	12,884
G	760	0	0	0	11	292	19,640	439	0	21,142
H	12,214	59	46	0	0	230	378	11,679	0	24,606
I	836	576	0	0	0	0	0	446	2,735	4,593

A second concern was that the frequency matrices allow the identification of interstate LMA's where appropriate. Thus, we decided on a substantial geographic overlap that allowed each county to be observed well away from the fringe of an analyzed area. In practice, this meant including States along the geographic fringe of one frequency matrix in a second matrix as well.

In view of this redundancy of States (and therefore counties), a final concern was that the number of frequency matrices be minimized by including as many States as possible in each. It was determined that the largest frequency matrix that could be manipulated by computer was 1,000 x 1,000 counties. Thus, another consideration was designing matrices that included States with enough counties to approach a total of 1,000.

Given these concerns, the six frequency matrices described in table 3 were constructed. The first matrix pertains to the Western States. While the number of counties does not approach the limit, the counties represented in the matrix do tend to be larger and less populated than those in the Eastern States. The overlap of States is plainly evident in the matrix for the Southwest. New Mexico, for example, was included in both the western and southwestern matrices. Analysis results based on the western matrix were used to place western New Mexico counties in LMA's, and results from the southwestern matrix were used to delineate markets in eastern New Mexico.

The matrix for the Central States was constructed to ensure redundancy of counties in the central part of the country. The remaining matrices--Midwest, Northeast, and Southeast--included as many States as possible without exceeding the 1,000-county ceiling. To summarize, six frequency matrices were constructed for the Nation. Except for the West, the strategy was to include as many States (and counties) as possible to overlap analysis boundaries by an entire State.

Since the number and geographic range of commuting destinations varied widely, destinations not among the set of origin counties in each matrix were deleted from the analysis. The western matrix, for example, covers the western third of the Nation. Even though Cook County, Illinois, was a reported commuting destination for several counties such as Los Angeles and Orange of California, Cook County does not appear in the frequency matrix that includes California. This strategy excluded evidence of extreme distance commuting, and eliminated some presumably nonroutine commuting patterns from the analysis. The result was manageable, square frequency matrices that contained the same number of rows and columns. Finally, in place of actual row totals, local resident labor force totals from the 1980 Census were used in the six frequency matrices. This practice ensured a constant labor force total for counties appearing in more than one frequency matrix.

Returning to the illustrative frequency matrix in table 2, we can safely say that the matrix provides interesting information on

Table 3--Frequency matrices encompassing 50 States and District of Columbia

Region	Number of counties	States included
West	493	Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, Utah, Washington, Wyoming
Southwest	670	Arkansas, Colorado, Kansas, Louisiana, New Mexico, Oklahoma, Texas
Midwest	913	Arkansas, Colorado, Iowa, Kansas, Minnesota, Missouri, Montana, Nebraska, North Dakota, Oklahoma, South Dakota, Wyoming
Central	765	Arkansas, Illinois, Iowa, Kentucky, Minnesota, Missouri, Tennessee, Wisconsin
Northeast	955	Connecticut, Delaware, District of Columbia, Illinois, Indiana, Kentucky, Maine, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, Vermont, Virginia, West Virginia, Wisconsin
Southeast	974	Alabama, Arkansas, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Virginia

commuting within a set of counties. These raw frequencies, however, are subject to a variety of alternative interpretations. First, the frequency matrix is not symmetric. The top half of the matrix in table 2 suggests that the commuting tie between county B and county A is over five times as strong as the commuting tie between counties E and A. That is, there are 857 workers who commute from B to A, compared with 168 workers who commute from E to A. In sharp contrast, the bottom half of the matrix indicates that the tie between B and A is only one-third as strong as the tie between E and A. (County A sends 1,827 workers to B and 5,132 workers to E.)

Since a local labor market has been defined in this analysis as a relatively self-contained area in which people live and work, the measure used here to delineate labor market areas includes numbers of commuters from both halves of the matrix: both the number of persons who live in a county and work elsewhere plus the number of persons who work in the county and live elsewhere. In table 2, the number of commuters from county B to county A (857) plus the number of commuters going the other direction (1,827) gives us a measure of the total shared commuters between counties A and B. This combined measure of shared commuting indicates that the total amount of interchange between counties A and E is almost twice as large as the interchange between counties A and B.

A second source of alternative interpretations of the frequency matrix lies in the variations in county labor force size. In table 2, the total amount of shared commuting between counties B and A (2,684) is very similar to the total shared commuting between counties D and A (2,108). However, the shared commuting between B and A represents only 5 percent of B's resident labor force, whereas the shared commuting between D and A represents over 11 percent of D's resident labor force. Thus, two very similar counts of commuters mask rather different journey-to-work patterns and substantially different relationships between counties. To avoid such misinterpretations, we derived a flow measure expressing the shared commuting patterns as proportions rather than absolute frequencies.

Flow Matrices. To adjust for county population differences, we computed a proportional flow measure for each pair of counties in a frequency matrix:

$$\frac{(\text{commuters from county } i \text{ to county } j) + (\text{commuters from } j \text{ to } i)}{(\text{resident labor force of smaller county})}$$

This results in a measure of shared commuters and is interpreted as a gauge of the strength of the commuting relationship between any two counties. These measures of association between counties were

calculated for each pair of counties in a frequency matrix using the formula:

$$P_{ij} = P_{ji} = \frac{(f_{ij} + f_{ji})}{\min(f_{i.}, f_{j.})}$$

where  $P_{ij}$  = the proportional flow measure for origin county  $i$  and destination county  $j$ ,  $f_{ij}$  = the number commuting from  $i$  to  $j$ ,  $f_{ji}$  = the number commuting from  $j$  to  $i$ ,  $f_{i.}$  = the origin row total, and  $f_{j.}$  = the destination row total. 3/

Several issues were involved in the choice of this particular flow matrix. As stated earlier, the numerator reflects a concern for the total number of commuters between two counties (regardless of direction) and, as such, provides a measure of the degree of interconnectedness between them. The denominator expresses the volume of shared commuters on a relative rather than absolute basis, thus ensuring that the analysis is not dominated by large counties. The resident labor force (as opposed to the working, or daytime, labor force) is used as the base because it is not sensitive to the direction of commuting and because it is constant across all versions of frequency matrices.

The smaller county's resident labor force in the denominator ensures that even highly asymmetric commuting patterns are considered evidence of a strong labor market tie. Thus, while commuters from a small county may make up only a minor portion of a large county's labor force, those same commuters can represent a very substantial proportion of the smaller county's resident labor force. We believe that such an asymmetric relationship is noteworthy. The counties clearly depend on each other in ways that have important social, economic, and political implications. Use of the large county's resident labor force or the sum of the two counties' labor forces would average the asymmetric relationship and reduce the apparent relationship between the two counties. 4/

A symmetric matrix of flow measures is a classic example of a similarity matrix. Each cell entry indicates how similar (or how strongly

---

3/ While the flow measure is characterized here as a proportion, it is technically a ratio which can exceed 1.0 when the number of commuters is greater than the smaller county's resident labor force. Ratios greater than one were entered in matrices as 0.999 for analysis purposes.

4/ In some preliminary analyses, we experimented with a flow measure that had as its denominator the sum of the two resident labor forces. In the case of a very large county paired with a very small county, analysis results were unsatisfactory because relationships between large and small counties were systematically underestimated.

related) any two counties are. Table 4 is the flow matrix for the frequency matrix in table 2. The main diagonal in table 4 refers to relationship of a county with itself and is not of concern since our objective is to group counties based on intercounty commuting ties. Note also that the similarity matrix is symmetric; the same flow measure appears for each pair above and below the diagonal. The first row pertains to county A. County H has the strongest commuting relationship with A. County F is next with a flow measure of 0.576, and county G is least associated with A. Flow matrices constructed from each of the frequency matrices were used as similarity matrices in the delineation analysis.

Table 4--Symmetric flow matrix for nine sample counties

County of residence	County of destination									
	A	B	C	D	E	F	G	H	I

Note: --- = flow coefficients were not computed for intracounty commuting.

#### Identification of Labor Market Areas

At the outset, it was agreed that three general guidelines would govern the delineation process:

1. Counties with commuting links were to be grouped into LMA's using flow matrices constructed from 1980 Census data.
2. Due to prevailing Census confidentiality standards, all LMA's were to encompass at least 100,000 persons.
3. Geographic detail was to be maximized.

Each of these criteria was linked to specific needs of those affiliated with Project S-184. One important objective of the

research committee was to obtain a public-use version of 1980 Census data that grouped counties into reasonable labor market areas. Since the Census Bureau would not identify places of fewer than 100,000 persons, the labor market areas conformed to this population restriction. Where the criteria would permit, we attempted to provide considerable geographic detail. Researchers hope to focus their efforts on particular market areas and to undertake comparative work on specific kinds of markets. This geographic detail was achieved primarily through the identification of market subareas with larger LMA's.

To aid in grouping counties, we employed a statistical procedure known as hierarchical cluster analysis.<sup>5/</sup> The cluster algorithm forms successively larger groups of items based on a degree of association between items. In this case, the items were counties and the association between them was the extent of commuting. Each of the six flow matrices was cluster analyzed separately, and the results were used to group counties into LMA's.<sup>6/</sup> The clustering program produces a tree-like diagram known as a dendrogram that indicates the pattern of clusters derived from a similarity matrix. Employing the criteria listed above, county clusters containing at least 100,000 persons were identified.

Illustrative Cluster Analysis. Figure 1 contains a dendrogram resulting from a hierarchical cluster analysis of the flow matrix in table 4. At the outset, the nine counties constitute nine separate "clusters." The diagram details the order in which clusters are combined into ever larger clusters. The vertical axis indicates the distance or degree of relationship between clusters. The greater the distance, the greater the dissimilarity in commuting relationships between any two groups. Clusters joining in the lower portion of the diagram are more strongly related to one another than those joining near the top of the figure (as they approach the vertical distance axis maximum).

The pair of counties with the strongest relationship (least distance) is joined in a cluster first. In the example, counties A and H exhibit the most similarity or, conversely, the least distance (0.40) of any county pair. The next strongest relationship (or least distance) is between the cluster of A and H

---

<sup>5/</sup> For an overview of cluster analytic techniques, see Aldenderfer and Blashfield (1984). The computer program employed in this analysis was the SAS procedure CLUSTER (SAS Institute Inc., 1985).

<sup>6/</sup> The SAS CLUSTER procedure requires matrix input in the form of a distance (dissimilarity) matrix. Thus, the analyzed matrices consisted of one minus the flow measure introduced above. An average linking algorithm was employed.

and county F which has a strong tie with A (review table 4). The next cluster to form contains counties B and I as the distance measure approaches its maximum (1.0). After formation of that cluster, counties E and C enter the original cluster containing A, H, and F.

By construction, the algorithm proceeds until it has grouped all counties in a final, all-encompassing cluster. The weakest linked counties, D and G, join only at the end of this agglomeration process. The "orphaned" status of counties D and G is quite predictable on the basis of the flow matrix (table 4) as they relate only weakly, at best, with any of the other counties. The formation of county clusters has been observed thus far without regard for population. The following section explains procedures that were used to accommodate the 100,000 population criterion.

Identifying LMA's on a Dendrogram. Dendograms for six flow matrices were used to identify LMA's. Clusters of counties were generally designated LMA's if the combined population exceeded our 100,000 criterion. However, clusters of counties did not reach this population minimum at the same point in the analysis. Counties within major metro areas often had populations greater than 100,000 by themselves. Thus, many major metro areas were divided into multiple clusters of counties, each satisfying the population criterion, but with a high degree of interconnectedness between them. In contrast, counties in sparsely settled areas tended to have a relatively low degree of interconnectedness and to form clusters somewhat later in the analysis.

To maintain consistency in the degree of interconnectedness of LMA's, we used the normalized average distance between clusters (displayed on the righthand side of the dendrogram) as a guide. As a rule of thumb, a normalized average distance of 0.98 was considered sufficient distance between sets of counties to treat them as separate LMA's (providing they met the 100,000 population criterion). Those counties with commuting relationships strong enough to make them cluster at a normalized distance of less than 0.98 were considered to be parts of the same LMA.<sup>7/</sup>

In figure 1, the A-H cluster satisfies the population criterion and can be designated an LMA. However, the commuting relationships between counties F and E and the A-H cluster are strong enough that they cluster before the 0.98 cutoff. Thus, the A-H county group is expanded to include counties F and E. County C has fairly weak commuting relationships with all of the other counties; but with a population of 41,000, it cannot stand alone. Since county C clusters with the A-H-F-E group before it clusters with any of the other counties, C is included in this county group.

---

<sup>7/</sup> While the SAS program normalized each matrix separately, the average distance between those counties included in multiple matrices was constant.

Reading across the figure to the right, B and I stand alone as a separate cluster with a combined population of over 100,000. Furthermore, the distance between the B-I cluster and the A-H-F-E-C cluster is greater than 0.98. Thus, the placement of these two counties into a separate LMA is justified both in terms of the population counts and in terms of sufficiently divergent commuting patterns.

Orphan counties D and G do not have populations in excess of 100,000 and therefore cannot be single-county LMA's. As the map in figure 2 indicates, D and G are fringe counties in this illustrative analysis. They quite likely exhibit stronger commuting ties with counties not included in the example. In practice, assignment of counties D and G to LMA's would be deferred until they could be analyzed in other matrices along with adjacent counties to the north and east. If these orphan counties did not cluster with other counties in any matrix, they would be assigned to an LMA on the basis of adjacency.

This example illustrates methods employed to designate LMA's with cluster analysis dendrograms. Closely related clusters with local populations exceeding 100,000 persons were identified as LMA's. The hierarchical aggregation patterns evident in the dendrograms were used to place counties that were not members of original clusters. Finally, steps were taken to ensure that breaks between clusters were defined consistently across all analyses through the use of a distance metric.

This analysis process culminated in the identification of 382 LMA's in the 50 States and the District of Columbia. Each commuting area was assigned an arbitrary, unique three-digit code beginning with 001 and continuing through 382. Once the cluster analysis results had been used to identify LMA's, further steps were taken to maximize geographic detail within the commuting areas. Procedures used to delineate subareas are described in the next section.

#### Delineation of LMA Subareas

One important objective of this analysis was to facilitate the study of relatively small areas. In many cases, the clusters of counties proved to be quite large in terms of population and number of counties, and efforts were made to identify fractions of the original LMA's. The following criteria were used to subdivide market areas:

1. All subareas were to equal or exceed the 100,000 population criterion.
2. Counties exceeding 100,000 in population were designated as single-county subareas, if possible.

Figure 2--Sample LMA delineation for nine counties

- county line
- LMA boundary
- - - Subarea boundary

3. Counties with fewer than 100,000 people were grouped with adjacent counties until the subarea population exceeded the criterion.

Attempts were made to subdivide each LMA containing a 1980 population in excess of 200,000. The five-county LMA identified in the example above would be partitioned into subareas as indicated in figure 2. The large counties (A and H) would be designated as subareas one and two. The other subarea indicated is composed of the remaining counties C, E, and F whose combined population exceeds 100,000. This set of counties would be subarea number three. The LMA consisting of counties B and I cannot be partitioned into subareas because of insufficient population.

Subdividing LMA's in this manner allows urban fringe areas to be differentiated from highly urbanized areas. Likewise, populous counties can be isolated for intensive analyses. The application of these subdivision criteria to the 382 LMA's yielded 875 subareas. Each subarea within an LMA was assigned a unique two-digit code that was appended to the three-digit LMA code. The arbitrary subarea codes begin with 01 and continue in sequence. LMA's with no subareas are assigned a suffix of 00. Thus, the five-digit code for any locale indicates the LMA of which it is a part and any subarea designation.

#### LABOR MARKET AREA CHARACTERISTICS

The delineation of these LMA's, and the availability of data sets that use the LMA's, offer a unique set of research opportunities, especially for researchers interested in rural or nonmetro labor markets. Past research on nonmetro areas has tended to be limited to one of two approaches. Results from the first approach--individual level analyses--have shown that the labor force experiences of individuals in nonmetro areas differ significantly from those in metro areas. However, these analyses have not been able to distinguish between different types of nonmetro areas. In contrast, results from the second approach--aggregate level analyses of county characteristics--have shown that there is a great deal of variation among nonmetro areas. These analyses however, have not been able to describe the characteristics or experiences of the individuals living and working in the county.

A major research question that can now be addressed with the LMA's is how the labor force experiences of people in nonmetro areas are mediated by the social and economic characteristics of the particular labor market in which they live and work. The special census file (the PUMS-D) will allow social scientists to place individuals within this context of the local labor market. In addition, there are many, rich sources of county-level data that can be aggregated to describe the diversity in the social and economic structures of labor market areas.

Participants in the USDA Project S-184 have already begun to develop detailed statistical profiles of the LMA's that can be used in

aggregate, ecological analyses or in conjunction with analyses of the individuals and households on the PUMS-D data file. We present some preliminary aggregate statistics here to help introduce researchers to these LMA's.

#### Location and Size

An overview of the size and distribution of the 382 LMA's and their subareas is provided in table 5. A rough approximation of the geographic distribution of the LMA's across the four census regions is shown in the first section of this table. (The LMA's were not constrained to follow State boundaries, so they do not correspond exactly to the census regions.) The South census region contains the most LMA's (over 45 percent), followed by the North Central region with 29 percent. The two remaining regions, the West and the Northeast, contain 14.9 percent and 10.5 percent. This geographical distribution of the LMA's corresponds fairly closely to the distribution of counties across the four regions. (The South contains 45.4 percent of all U.S. counties, the North Central contains 33.6 percent, the West contains 14 percent, and the Northeast contains 6.9 percent.)

The remaining sections in table 5 refer to the average size of the LMA's and their subareas, both in terms of population and the number of counties. Column 1 in table 5 shows descriptive statistics for all of the LMA's taken together. The average population size of all the LMA's is just under 600,000 and the standard deviation is over 1.1 million. Since the population figures tend to be highly skewed, the median population size--roughly 270,000--is a more accurate description. The mean number of counties in an LMA is 8.2 and the median number is 7. In sum, making use of the median figures, we can say that the typical LMA encompasses seven counties and just under 300,000 inhabitants.

The next four columns in table 5 show that the size of the LMA's varies considerably by region. The North Central region has the smallest LMA's in terms of total population size, but the largest LMA's in terms of the number of counties. In contrast, the LMA's in the densely populated Northeast have the fewest number of counties and the highest average population size. <sup>8/</sup> The average population size of the LMA's in the West shows the greatest relative variation, with geographically

---

<sup>8/</sup> The largest LMA in terms of population, the New York City area, contains 11,786,933 people, and only 11 counties, whereas the LMA with the largest number of counties, located primarily in Nebraska, has 34 counties and a population size of 310,766.

Table 5—The location and size of LMA's in the United States

Item	Total (1)	West (2)	South (3)	North Central (4)	Northeast (5)	Subareas (6)

Largest LMA	34	23	26	34	11	28
Mean county population	72,218	100,063	52,773	55,175	221,025	73,974

small, but densely populated LMA's along the Pacific coast, and geographically large, but sparsely populated LMA's in the interior.<sup>9/</sup>

And finally, the population figures in the last column of table 5 show that the 875 subareas of the LMA's provide a substantial amount of geographic detail. The average subarea contains about 260,000 residents, or roughly half the mean number of persons in the average LMA. Similarly, the median population of the subareas is about 150,000, just over half that of the LMA's. The largest subarea, Los Angeles, California, is also the largest U.S. county. The smallest subarea, a county group located in west Texas, has only 87 more persons than the minimum of 100,000. The mean number of counties per subarea is 3.6 and the median is 2, although 328 subareas (37 percent) are single counties.

#### Rural (or Nonmetro) Labor Market Areas

Urban/rural and metro/nonmetro are often used interchangeably in describing the residence of populations. However, the terms reflect very different classification criteria. Urban and its counterpart, rural, are based on population density. The urban population generally comprises people living in cities and towns with 2,500 or more inhabitants, or in areas with 1,000 or more persons per square mile. The remaining population is rural. In contrast, MSA's (Metropolitan Statistical Areas) are counties classified on the basis of both population density (in the form of a large, densely populated nucleus with at least 50,000 inhabitants) and economic and social ties with surrounding counties (primarily in the form of commuting to the central counties). Counties not included in an MSA are classified as nonmetro. These two classification schemes are clearly not equivalent: the population in a small town of 3,000 residents is distinctively different from the population in a large metro area, yet they are both classified as urban. Moreover, there is quite a bit of overlap between the two schemes. Metro counties sometimes include a considerable number of rural residents, and nonmetro counties often include a large number of people living in small towns and cities.

As noted earlier in this report, the strategy for delineating the LMA's permits, at least in principle, the study of rural or nonmetro as well as urban or metro labor markets. The question remains, however: "How

---

9/ The coefficient of variation for population size (the standard deviation of the mean population of the LMA's expressed as a percentage of that mean) for the West is 213 percent compared with 174 percent for the North Central, 164 percent for the Northeast, and 117 percent for the South. The coefficient of variation for the number of counties is 63 percent in the West, 61 percent in the North Central, 54 percent in the South, and 47 percent in the Northeast. Large coefficients of variation indicate a large amount of variation within a region around the average size of the LMA's in that region in terms of population and number of counties.

many of the 382 LMA's are in fact rural or nonmetro?" In table 6, we suggest one classification scheme that can be used to answer this question. This breakdown incorporates both the nonmetro/metro classification of the counties making up each LMA and the rural/urban characteristics of its residents.

Table 6--A rural-urban/nonmetro-metro classification of LMA's

Population	Number of LMA's with--				Total
	All nonmetro counties	At least 1 small or medium metro county	At least 1 major metro county		
Greater than or equal to 50-percent rural	104	48	0		152
Less than 50-percent urban	30	153	47		230
Total	134	201	47		382

The metro/nonmetro dimension in table 6 shows that 134 of the 382 LMA's (35 percent) do not contain any metro counties. Over half of the LMA's contain at least one small- to medium-sized metro county (but no major metro county). 10/ The remaining 12 percent of the LMA's contain a major metro county. The second dimension in table 6 further breaks down the LMA's according to where the residents of the LMA live. In 40 percent of the LMA's, at least half of the population lives in a rural area. In the other 60 percent, over half lives in an urban area. The cross-classification of these two dimensions results in the following five (out of six possible) categories: 11/

Rural nonmetro	All of the counties in the LMA are nonmetro and 50 percent or more of the population is rural;
Urban nonmetro	All of the counties in the LMA are nonmetro and more than 50 percent of the population is urban;
Rural metro	The LMA contains (at least) one small- to medium-metro county (and no major metro county and 50 percent or more of the population is rural;

10/ Major metro counties are the central and fringe counties of MSA's with 1 million or more population. Medium and small metro counties are counties in metro areas with populations under 1 million. (See Hines, Brown, and Zimmer, (1975) for a description of the size of MSA's.)

11/ No LMA's fell into the sixth, rural-major metro category.

Urban metro      The LMA contains (at least) one small- to medium-metro county (and no major metro county and more than 50 percent of the population is urban;

Major metro      The LMA contains (at least) one major metro county and more than 50 percent of the population is urban.

These five categories are not intended to represent a uni-dimensional ranking of LMA's. The set of LMA's chosen for analysis must ultimately depend on the needs and interests of the researcher. Nevertheless, this preliminary classification does demonstrate that the procedure used to delineate the LMA's did in fact produce a large number of "nonmetro" or "rural" LMA's. There are 104 LMA's that fit the most stringent definition of "rural nonmetro," and using a looser definition--LMA's in which either 50 percent or more of the population is rural or all of the counties are nonmetro--we can consider almost half of the LMA's to be "rural" or "nonmetro."

#### Economic and Social Characteristics

The final set of descriptive statistics for this preliminary profile of the LMA's emphasizes the importance of both the metro/ nonmetro and the urban/rural dimensions in this classification scheme (table 7). The percentage black in the urban nonmetro LMA's, which are located

Table 7--Social and economic characteristics of LMA's 1/

Item	Rural		Urban		
	Nonmetro	Metro	Nonmetro	Metro	Major metro
<u>Percent</u>					
Black	9.5	8.2	4.7	10.1	12.2
Completing:					
High school	56.7	58.8	65.9	64.4	69.9
College	10.5	11.3	14.2	14.4	17.9
Unemployment rate	8.5	8.4	7.6	7.0	6.8
Poverty rate	17.0	14.1	15.3	13.6	10.6
<u>Dollars</u>					
Per capita income	7,163	7,606	8,082	8,528	10,269

1/ All data are from the 1980 Census of Population.

primarily in the West, is much smaller than in any of the other LMA categories, and is only half as large as the percentage black in the other nonmetro category (rural nonmetro).

The percentage of the population 25 years and older who have completed high school and the percent who have completed college are lowest in the two rural categories, but the educational attainments in two of the urban categories are also relatively low compared with those in the major metro LMA's. The rural/urban distinction appears to be most important in terms of unemployment rates, with both the metro and nonmetro types of rural LMA's having higher rates than any of the predominantly urban LMA's. Similarly, per capita incomes are lowest in the two rural areas, although there are also notable differences in per capita income between the nonmetro/metro/major metro categories. In contrast, the greatest differences in poverty rates are found between the nonmetro/metro types of LMA's.

In sum, these preliminary statistics have provided a brief introduction to the LMA's: their size, location, and a few of their social and economic characteristics. In addition, they have provided support for the argument that nonmetro (or rural) America can not be treated as a single homogeneous category.

#### CONCLUSIONS

The labor market identification process reported here was a necessary, but preliminary phase of work planned by those affiliated with Project S-184. Project researchers are using the acquired Census data (PUMS-D) to address a number of issues. To infer attributes of local organization of production, researchers are mapping the industrial and occupational mixes of market areas. One result of these efforts will be the identification of LMA's dominated by single industries or single commodities. How employment in these areas differs from that in other multi-industry areas will be assessed.

Basic demographic profiles are being prepared and area socioeconomic characteristics are being surveyed to determine the extent of local inequality. This research can lead to generalizations about poverty and unemployment in similar market areas and can aid our understanding of variations from one market to another. The inventory efforts will yield data that can be used to classify market areas in a variety of typologies. As we have seen in data presented here, one important classification involves a differentiation of nonmetro labor markets. From our preliminary evidence, we can readily conclude that it is a mistake to assume homogeneity in work environments throughout nonmetro America.

Researchers are also focusing on families and households in nonmetro market areas. Using the LMA scheme and the PUMS-D, some investigators are comparing household characteristics of metro and nonmetro families. Another theme of research is the extent of off-farm labor and its

relationship to agricultural work by family members. Results from these studies can be used to draw parallels between families whose primary source of support is agriculture and families who rely on other industries.

A massive historical county data file is being assembled by S-184 participants. Efforts are aimed at producing a time-series data bank for American counties that takes into account changes over time in county boundaries (Horan, Hargis, and Killian, 1987). Once the county-level data file is complete, the information can be aggregated into groups of counties that correspond to the LMA scheme. Researchers will then be able to trace changes over time in market areas and associate these changes with information on individuals in the Census data file.

The geography and associated Census data file are in the public domain. PUMS-D can be obtained directly from the U.S. Bureau of the Census. Those desiring rectangular or other special versions (including a national labor force extract file) should contact the Social Science Computing Program at Florida State University. Representatives of academic institutions affiliated with the Interuniversity Consortium for Political and Social Research may obtain the data from ICPSR.

Other researchers and policy analysts are encouraged to use the geography and data. In particular, we suspect that local officials may find the labor market area specification useful in their assessments of regional employment policies. We are not aware of any plans for a comparable 1990 Census data file. If there were to be one, it would not be available for several years hence. In the interim, those of us participating in Project S-184 invite others to join us in exploiting the promise of PUMS-D and its unique labor market geography.
